

Vectors.

- are much like arrays.
- operations on vector - same big O as on arrays.
- array with dynamic size.
- the size can be increased or decreased as you add or remove elements from/to it.

index	0	1	2	3
element	10	2	3	9

eg: find highest common factor of 2 no.s.

can't use array as we don't know how many factors are there for a specific number.

use vectors here.

vectors - do not reallocate memory to grow in size, everytime a new element is inserted. Instead,

it may allocate some extra storage to accommodate for possible growth.

different libraries - different complementations (for growth) to accommodate possible growth.

Vectors :

Collection of specific type.

vector < double > rainfall (7)

type name size

7 elements in this vector

	6.3	7.2	9.4	0	4.2	3	1.1
index	0	1	2	3	4	5	6

accessing vectors.

rainfall [4]

o/p :

4.2.

```
#include <vector>
```

```
vector<int> v(3);
```

```
v[0] = 6
```

```
v[1] = 9
```

```
v[2] = 4
```

6	9	4
---	---	---

dynamically add more elements

```
v.push-back(2);
```

0	1	2	3
6	9	4	2

```
cout << v.front();
```

6

```
" << v.back();
```

2

```
" << v[2];
```

4

```
v.at(2)
```

```
printvector(v);
```

fn:

void

```
printvector(vector<int> &v)
```

```
{
```

```

for (int i=0; i<b.size(); i++)
{
    b[i]
    cout << b.at(i) << endl;
}
}

```

C++ vector functions

at() → reference to an element

Swap() → exchanges the elements between two vectors.

push-back() - adds new element at end.

~~push~~ pop-back() - removes last element from vector

empty() - determines whether vector is empty or not.

insert() - inserts new element at a specified position.

^{determines}
size() - nos. of elements in array

Hash Tables

data structure, data is stored in array format.

each data value has its own unique index value.

Access of data becomes very fast, if we know the index of the desired data.

22 Sunday

022-343 Week 3

insertion & search operations are very fast, irrespective of the size of the data.

Hash Table

uses array to store.

uses hash functions / technique to generate the index. where the element has to be inserted

Hashing

Technique to convert a range of key values into a range of indexes of an array

eg: hash table of size 20.

(key, value)

key	Hash	Array Index	(key, value)
			(1, 20)
1	$1 \% 10 = 1$	1	(2, 70)
2	$2 \% 10 = 2$	2	(42, 80)
42	$42 \% 10 = 2$	2	collision (4, 25)
4	$4 \% 10 = 4$	4	(17, 11)
17	$17 \% 10 = 7$	7	(13, 78)
13	$13 \% 10 = 3$	3	(37, 98)
37	$37 \% 10 = 7$	7	collision

Linear search $O(n)$

Binary search $(\log n)$

$$h(k) = k \% m$$

↓

Size of hash table.

To resolve collisions there are techniques.

④ Collision - cannot be resolved. It can only be minimized.

MTWTFSS MTWTFSS MTWTFSS MTWTFSS

1. Open Hashing (Closed Addressing)

collision resolving

method is by Chaining

2. closed Hashing (Open Addressing)

to resolve collisions.

Linear
Probing

Quadratic
Probing

Double
Hashing

Chaining Method / closed addressing

each cell of hash table point to a linked list of records that have the same hash function value.

Simple

but requires additional memory outside the table.

Open Addressing

all elements are stored in the hash table itself.

Size of table must be greater than or equal to the total number of keys.

Chaining Technique

The idea is to make each cell of hash point table point to a linked list of records that have same hash function value.

Linear Probing

Open Addressing

insert(k): keep probing until an empty slot is found. Once empty slot is found, insert k .

search(k): keep probing until slot's key doesn't become equal to k or an empty slot is reached.

Delete(k): if we simply, delete a key, search operation may fail. So slots of deleted keys are marked specially as 'deleted'.

⇒ Insert can insert an item in a deleted slot.

29^{Sunday} but search doesn't stop at a deleted slot.

Linear Probing: linearly probe for next slot.

(key mod 7)

$u = (\text{key mod } 7)$

$i = \text{ranges from } 0 \text{ to } n-1$

for 92

$u = 2$

$(2+0)\%7 = 2; (2+1)\%7 = 2; (2+2)\%7 = 3$

main problem: takes time to find a free slot or to search an element.

in case collision

Insert k_0 at first free location from $(u+i)\%m$ where $i = 0$ to $m-1$

Quadratic Probing

In case of collision:

insert k_i at first free location from $(u + i^2) \% m$ where $i = 0$ to $m-1$.
